

CIRCLES

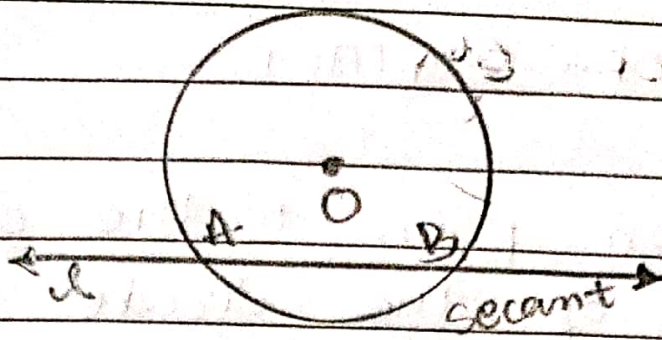

Circle is a collection or set or locus of points which are equidistant from fixed point.

The fixed point is called centre of circle and fixed distance is called radius of circle.

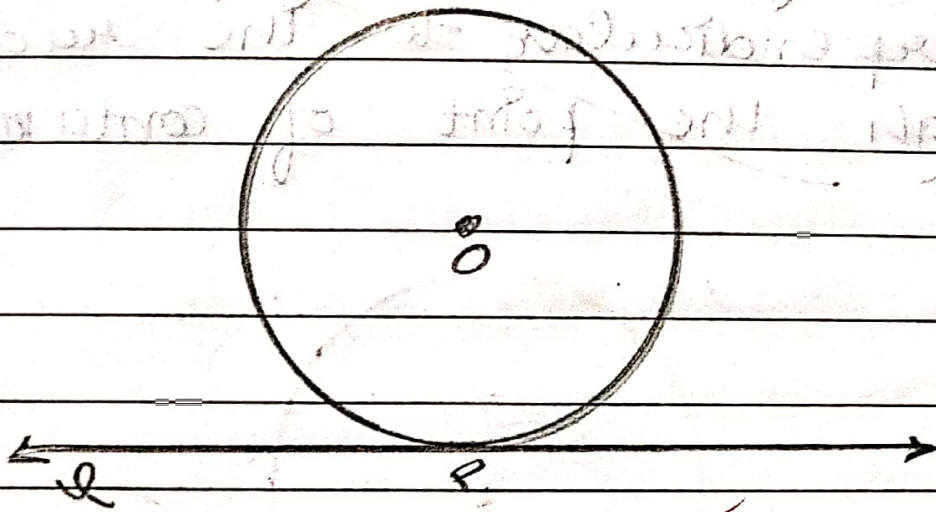

SECANT AND TANGENT OF CIRCLE

- ① A line which intersects a circle in two distinct points is called secant of circle.

A line which intersects the circle in one and only one point is called tangent to the circle.

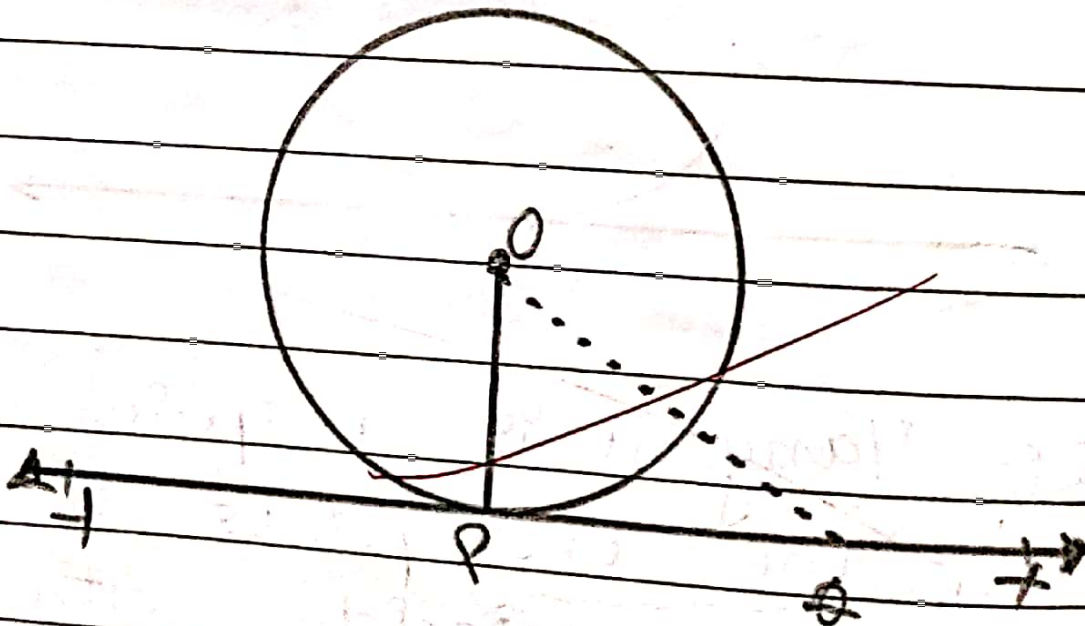

NOTE :- Tangent is a special case of secant when the end points of its corresponding chord are coincide with each other.

POINT OF CONTACT

A common point to the circle and tangent of the circle is called point of contact.

THEOREM 10.1

The tangent at any point of a circle is perpendicular to the radius through the point of contact.

Proof :-

If we consider points other than P, such as Q.

We'll find that OP is the shortest distance.

$$OP > OQ$$

Thus OP will be the perpendicular to XY.

$$OP \perp XY$$

Hence proved.

(i) A tangent to a circle intersects it in one point (s).

(ii) A line intersecting a circle in two points is called a secant.

(iii) A circle can have two parallel tangents at the most.

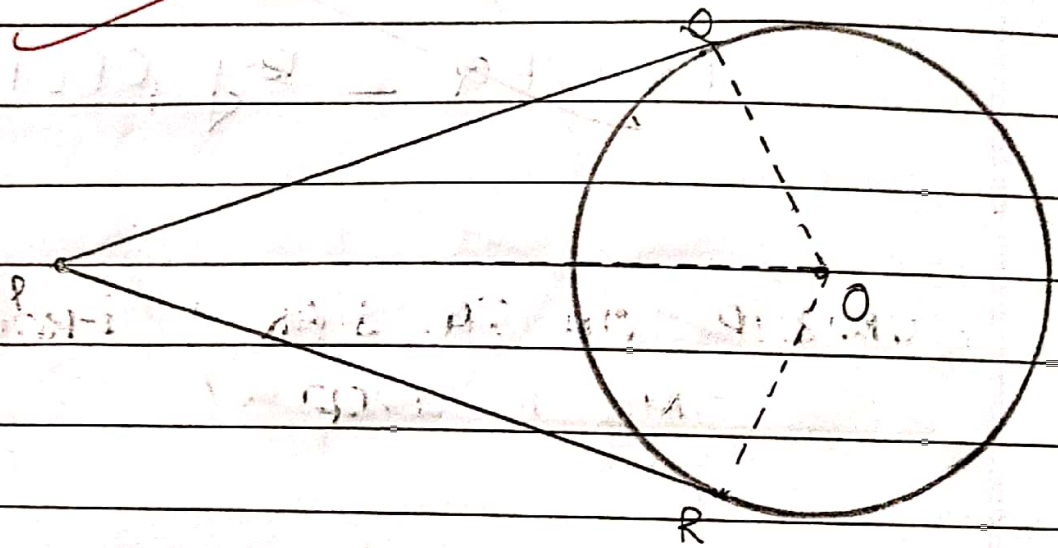

(iv) The common point of a tangent to a circle and the circle is called point of contact.

NUMBER OF TANGENTS FROM A POINT TO ON A CIRCLE

- ① There is no tangent to a circle passing through a point lying inside the circle.
- ② There is one and only one tangent to a circle passing through a point lying on a circle.

(3) There are exactly two tangents to a circle passing through a point lying outside the circle.

THEOREM 10.2 :- The lengths of tangents drawn from an external point to a circle are equal.

PROOF :-

Consider that a circle with center O and PQ and PR are the two tangents drawn from external point P to the circle.

We need to prove that $PQ = PR$.

Join OP, OQ, OR

By theorem,

$$PQ \perp OQ$$

$$PR \perp OR$$

∴ In right Δ's

$\triangle ORP$ & $\triangle OQP$

$$OP = OP$$

(Common side)

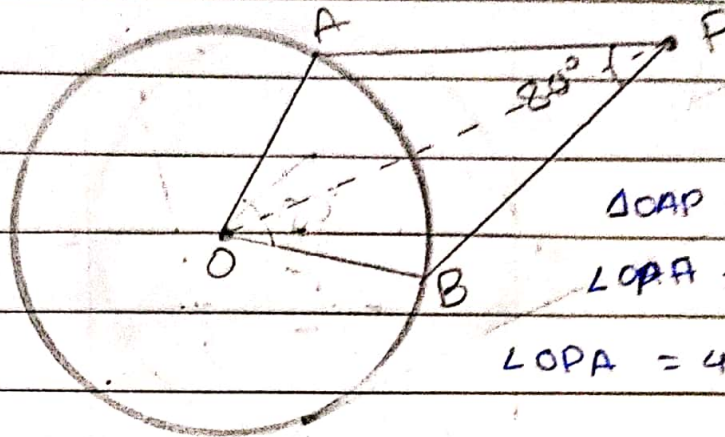

$$OR = OQ$$

(radii of same circle)

$\triangle ORP \cong \triangle OQP$ by RHS

~~$PR = PQ$ — By CPCT~~

If tangents PA and PB are equal to:

In $\triangle OAP$ and $\triangle OBP$,

$OA = OB$ (same radii)

$OP = OP$ (common)

$\triangle OAP \cong \triangle OBP$ (RHS Test)

$\angle OPA = \angle OPB$ (CPCT)

$\angle OPA = 40^\circ = \angle OPB$

OA and OB are the radii

$OA \perp AP$ & $OB \perp BP$

$\angle OAP = 90^\circ = \angle OBP$

In $\triangle OAP$,

$\angle OAP + \angle APO + \angle POA = 180^\circ$

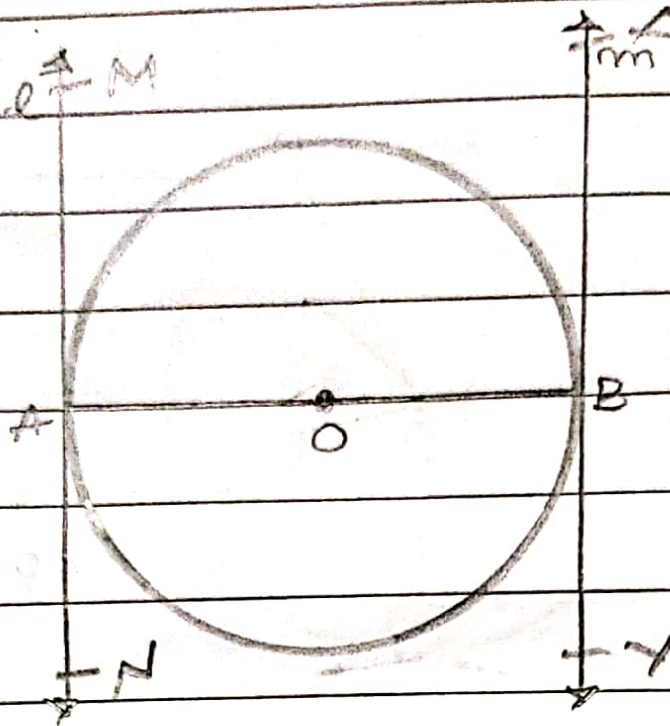

$90^\circ + 40^\circ + \angle POA = 180^\circ$

$130^\circ + \angle POA = 180^\circ$

$\angle POA = 50^\circ$

Prove

are parallel.

AB is the ~~radius~~ ^{diameter}. OA & OB are the radii.
XY & MN are the tangents.

$OA \perp MN$ & $OB \perp XY$.

$$\angle OAN = 90^\circ$$

$$\angle OAM = 90^\circ$$

$$\angle YBO = 90^\circ$$

$$\angle OBX = 90^\circ$$

$$\angle OAN + \angle YBO = 180^\circ$$

(Interior angles)

$$\angle OAM + \angle OBX = 180^\circ$$

(Interior angles)

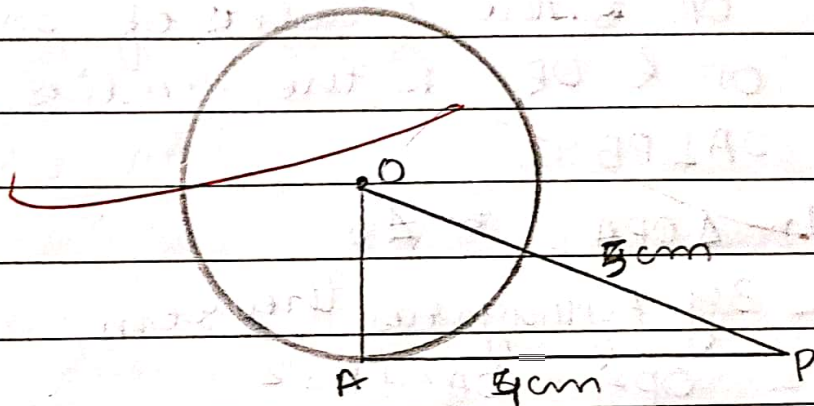

Interior angle

Sum of interior angles is 180° so, \therefore Test they are parallel to each other.

$\therefore XY \parallel MN$

Hence proved

6) The length _____ the circle.

OA is the radius.

$OA \perp AP$ (\perp to tangent)

By Pythagoras theorem,

In $\triangle OAP$,

$$OP^2 = OA^2 + AP^2$$

$$(5)^2 = OA^2 + (4)^2$$

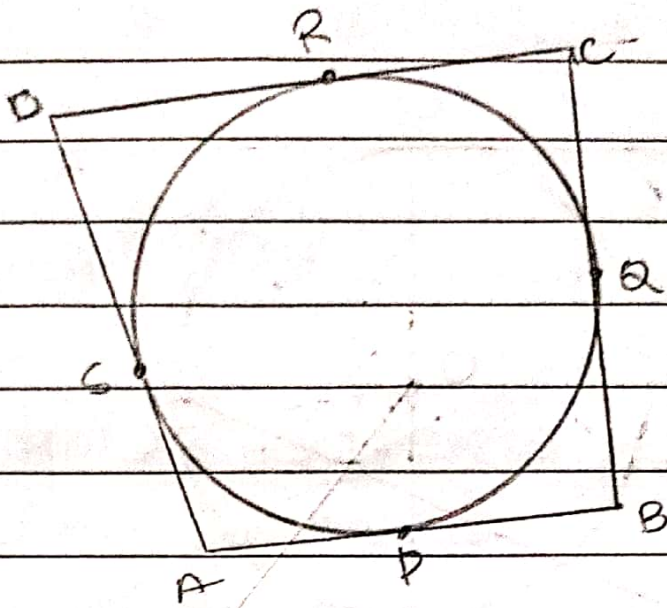

$$25 = OA^2 + 16$$

$$OA^2 = 9$$

$$OA = 3$$

\therefore Radius of circle = 3

A quadrilateral $ABCD$ $AB + CD = AD + BC$.

Tangents $AP, AS, DS, DR, CR, CQ, QB, BP$ are drawn from external points A, B, C, D .

$$AP = AS \quad \text{--- (1)}$$

$$DP = DR \quad \text{--- (2)}$$

$$CR = CQ \quad \text{--- (3)}$$

$$BQ = BR \quad \text{--- (4)}$$

Lengths of tangents from an external point are equal.

Adding equations,

$$AP + BP + CR + DR = AS + BQ + CQ + DS$$

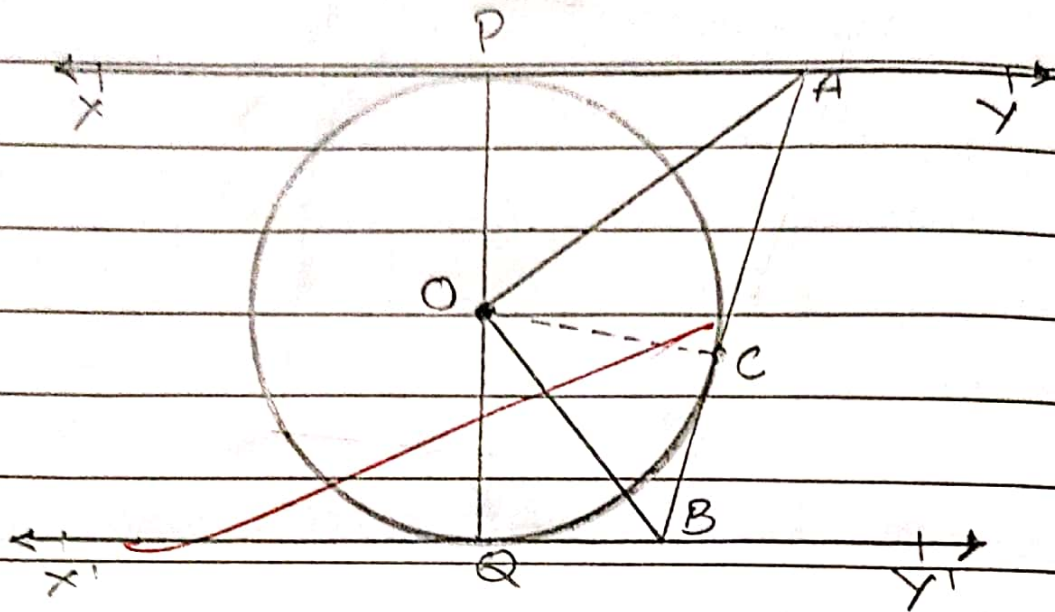

$$AB + CD = BC + AD$$

$$AB + CD = AD + BC$$

Hence proved

In fig

$$\angle AOB = 90^\circ$$

Join OC

$$OP \perp PA$$

$$OQ \perp BQ$$

$$OC \perp AB$$

} Tangent perpendicular radius

$$\therefore \angle OPA = \angle OQB = \angle OCA = \angle OCB = 90^\circ$$

In $\triangle OPA$ & $\triangle OCA$,

$$OA = OA \quad (\text{Common})$$

$$OP = OC \quad (\text{Radii of same circle})$$

$$\triangle OPA \cong \triangle OCA \quad \text{By RHS}$$

$$\angle POA = \angle AOC$$

C.P.C.T

$$\text{Let } \angle POA = \angle AOC = x \quad \text{--- (1)}$$

DATE: ___/___/___

PAGE No: _____

Similarly,

$\triangle OQB \cong \triangle OCB$ by RHS $\angle QOB = \angle COB$ (CPCT)

$$\therefore \angle QOB = \angle COB = y$$

$$\angle POA + \angle AOC + \angle BOC + \angle BOQ = 180^\circ \text{ (Linear pair)}$$

$$x + x + y + y = 180^\circ \text{ (from } \textcircled{1} \text{ \& } \textcircled{2})$$

$$2x + 2y = 180^\circ$$

$$2(x + y) = 180^\circ$$

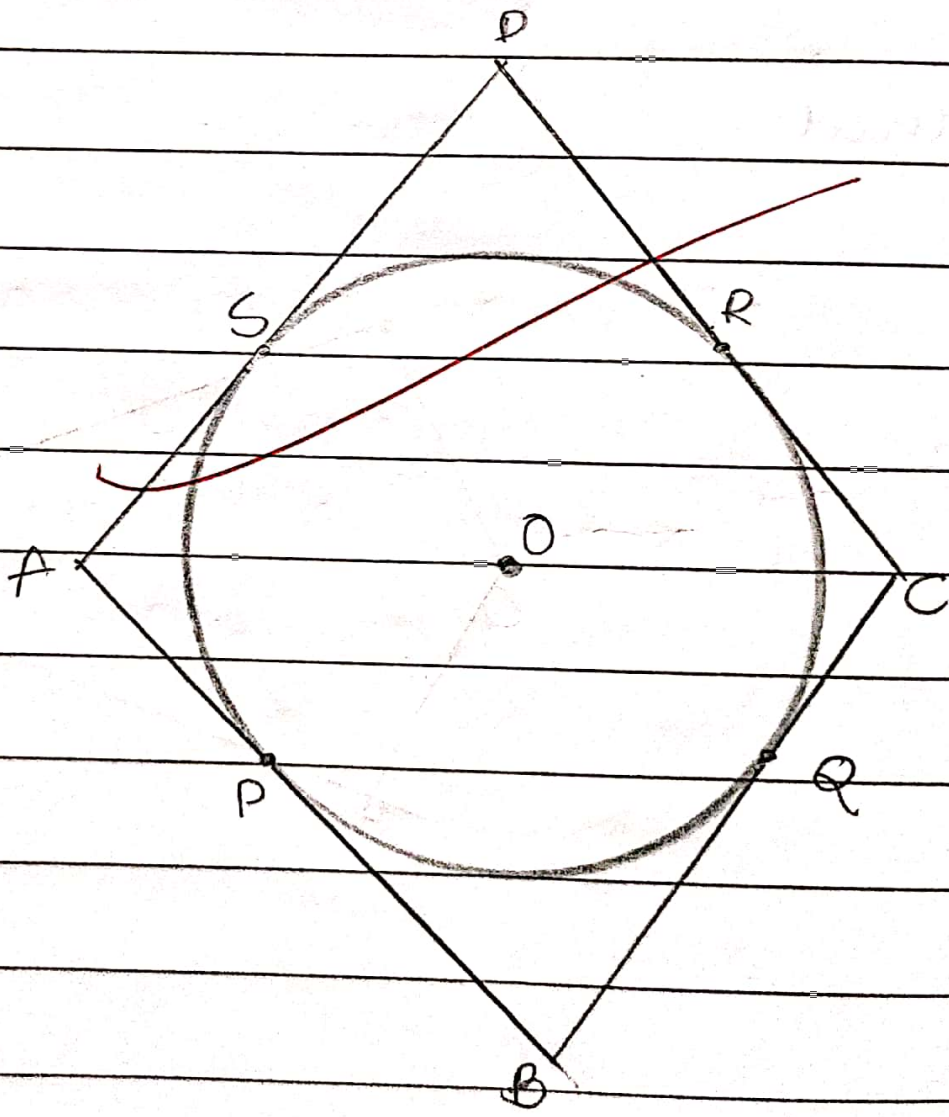

$$x + y = 90^\circ$$

$$\angle AOC + \angle BOC = 90^\circ$$

$$\angle AOB = 90^\circ$$

Hence proved

Prove - - - - rhombus.

→ ABCD is a parallelogram.

$$\therefore AB = CD \quad \text{--- (1)}$$

$$BC = AD \quad \text{--- (2)}$$

$$DR = DS$$

$$CR = CQ$$

$$BP = BQ$$

$$AP = AS$$

Tangents from external point

Adding all these,

$$DR + CR + BP + AP = DS + CQ + BQ + AS$$

$$DR + CR + BP + AP = DS + AS + CQ + BQ$$

$$CD + AB = AD + BC \quad \text{--- (3)}$$

Putting value of (1) & (2)

$$2AB = 2BC$$

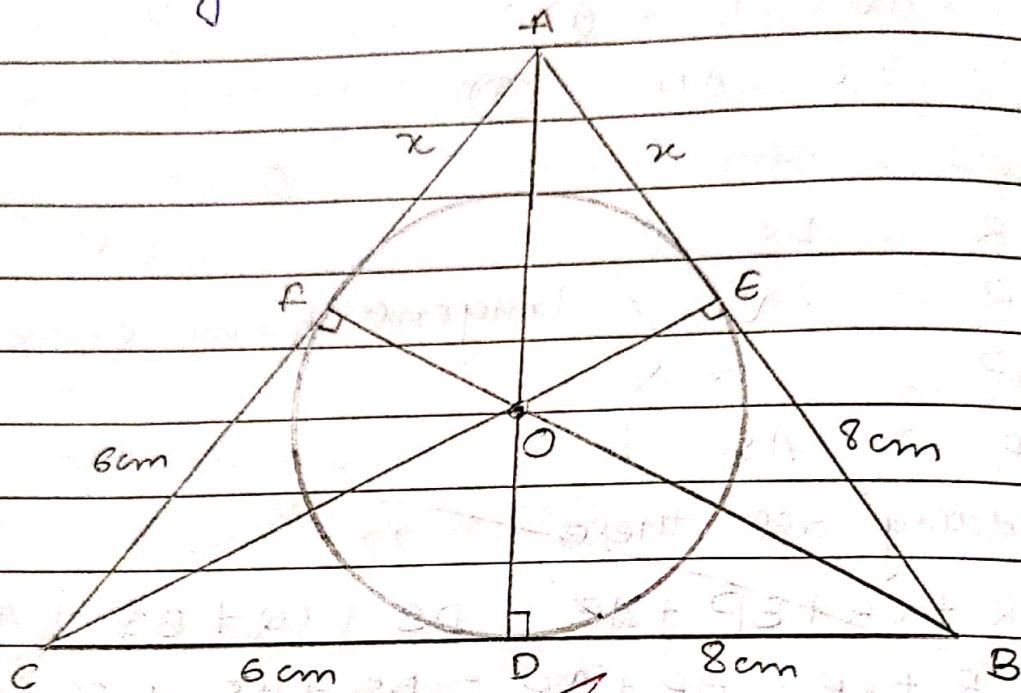

$$AB = BC \quad \text{--- (4)}$$

Comparing (1), (2) & (4) we get,

$$AB = BC = CD = DA$$

\therefore ABCD is a rhombus.

12) A triangle ABC with an inscribed circle. The circle touches side AB at E and side AC at F. The radius of the circle is x cm. The length of side BC is 14 cm. The length of side AB is 14 cm. The length of side AC is 14 cm. The length of side AB and AC is 14 cm.

In $\triangle ABC$,

$$CF = CD = 6 \text{ cm}$$

$$BE = BD = 8 \text{ cm}$$

$$AE = AF = x \text{ cm}$$

Tangents from external point

$$AB = AE + EB = x + 8$$

$$BC = BD + DC = 8 + 6 = 14$$

$$CA = CF + FA = 6 + x$$

Semiperimeter s ,

$$2s = AB + BC + CA$$

$$2s = x + 8 + 14 + 6 + x$$

$$= 28 + 2x$$

$$s = 14 + x$$

By Heron's formula,
In $\triangle ABC$

$$\begin{aligned} \text{ar}(\triangle ABC) &= \sqrt{s(s-a)(s-b)(s-c)} \\ &= \sqrt{(4+x)(14+x-4)(14+x-x-6)(14+x-4-x)} \\ &= \sqrt{(4+x)(x)(8)(6)} \\ &= \sqrt{(4+x)48x} \quad \text{--- (3)} \end{aligned}$$

$$\begin{aligned} \text{ar}(\triangle ABC) &= \frac{1}{2} \times BC \times AD \\ &= \frac{1}{2} \times 14 \times 4 \\ &= 28 \end{aligned}$$

$$\begin{aligned} \text{ar}(\triangle AOB) &= \frac{1}{2} \times AB \times OE \\ &= \frac{1}{2} \times 8+x \times 4 \\ &= 16+2x \end{aligned}$$

$$\begin{aligned} \text{ar}(\triangle AOC) &= \frac{1}{2} \times AC \times OF \\ &= \frac{1}{2} \times 6+x \times 4 \\ &= 12+2x \end{aligned}$$

$$\begin{aligned}
 \text{ar}(ABC) &= \text{ar}(COB) + \text{ar}(AOB) + \text{ar}(AOC) \\
 &= 28 + 16 + 2x + 14 + 2x \\
 &= 56 + 4x \quad \text{--- (2)}
 \end{aligned}$$

Equating (1) & (2)

$$\sqrt{(14+x)} \cdot 48x = 56 + 4x$$

Squaring

$$48x(14+x) = (56+4x)^2$$

$$48x = \frac{[4(14+x)]^2}{(14+x)}$$

$$48x = 16(14+x)$$

$$48x = 224 + 16x$$

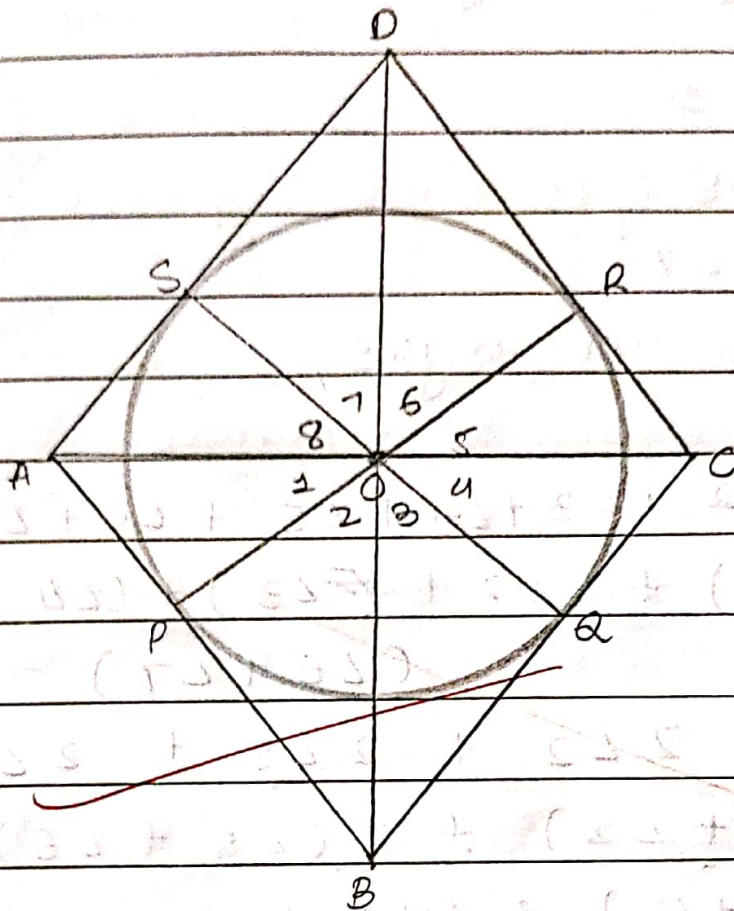

$$32x = 224$$

$$x = 7 \text{ cm}$$

$$\therefore AB = x + 8 = 7 + 8 = 15 \text{ cm}$$

$$AC = x + 6 = 6 + 7 = 13 \text{ cm}$$

Prove that \dots the circle.

Let ABCD be the quadrilateral.

P, Q, R, S are point of contact.

In $\triangle OAP$ & $\triangle OAS$,

$AP = AS$ (Tangent from external point)

$OP = OS$ (Radii)

$OA = OA$ (Common)

$\triangle OAP \cong \triangle OAS$ (SSS criteria)

$\therefore \angle POA = \angle AOS$ By CPCT

$\angle 1 = \angle 8$

Similarly we get,

$$\angle 2 = \angle 3$$

$$\angle 4 = \angle 5$$

$$\angle 6 = \angle 7$$

Adding all angles,

$$\begin{aligned} \angle 1 + \angle 2 + \angle 3 + \angle 4 + \angle 5 + \angle 6 + \angle 7 + \angle 8 &= 360^\circ \\ (\angle 1 + \angle 8) + (\cancel{\angle 2 + \angle 3}) + (\angle 4 + \angle 5) + & \\ & (\angle 6 + \angle 7) = 360^\circ \end{aligned}$$

$$2\angle 1 + 2\angle 4 + 2\angle 6 = 360^\circ$$

$$2(\angle 1 + \angle 4) + 2(\angle 6) = 360^\circ$$

$$(\angle 1 + \angle 4) + (\angle 6) = 180^\circ$$

$$\angle AOB + \angle COD = 180^\circ$$

Similarly, $\angle BOC + \angle DOA = 180^\circ$

Hence proved.
