

Surface Chemistry

- * It is branch of chemistry which deals with phenomena taking place at surface or interface. (gas-gas interface is not possible).
eg. rusting & crystallisation.

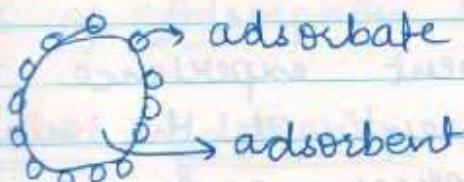

- * Adsorption : Accumulation of molecular species on surface of substance as a result conc. of species at surface becomes more than its conc. in the bulk.

- eg. - Dye sol" + charcoal
- Gases + charcoal
- Raw sugar + animal charcoal
- Water vapours + silica gel.

- * Adsorbate : Substances which get adsorbed.

- * Adsorbent : Substances on which adsorbate gets adsorbed

* Absorption : conc. of substance will be same throughout.

For eg.,

- CaCl₂ absorbs water vapour.

Note: rate of adsorption decreases with time while rate of absorption remains same throughout.

* Sorption : When both adsorption and absorption take place simultaneously.

For eg.,

- when a chalk is placed in any solution particles of dye (ink) get adsorbed on its surface while particles of solvent get absorbed in bulk.

* Desorption : Removal of adsorbate particles from surface of adsorbent.

* Negative adsorption : Particles of solvent get adsorbed. As a result conc. of solute in soln increases.

• Why adsorption takes place?

→ Particles present in adsorbent experience zero net force but particles present at the surface experience net inward forces and due to these unbalanced forces or rigid mass forces, those particles at surface attracts other particles. As a

decrease in surface energy takes place in form of heat released so adsorption is exothermic process.

- Thermodynamics of Adsorption :-

$$\Delta G = \Delta H - T\Delta S$$

where,

ΔG = change in Gibbs free energy

ΔH = " in Enthalpy

T = Temp.

ΔS = change in entropy / randomness

For spontaneous Process, $\Delta G < 0$

For non-spont. process, $\Delta G > 0$

$$\Delta G = \Delta H - T\Delta S$$

Spontaneity is driven by

- a) decrease in enthalpy
- b) increase in randomness.

During adsorption, entropy $\downarrow \Rightarrow \Delta S$ is -ve, still adsorption takes place, it means it is driven by enthalpy factor.

- Types of Adsorption :-

- i) Physical adsorption or physisorption :-

In it particles of adsorbate & adsorbent are held together by weak vanderwaal forces.

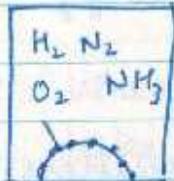

- characteristics of Physisorption :

a) It lacks specificity.

→ Physical adsorption is not specific in nature.

For eg.

charcoal can adsorb any of gases given

b) Extent of adsorption will depend on nature of adsorbate.

→ Easily liquifiable gases are adsorbed to a larger extent.

$$T_c = \frac{8}{27} \frac{a}{b}$$

$$T_c \propto a$$

larger the value of T_c, larger will be the forces of attraction & more easily a gas can be liquified.

For eg,

$$\begin{array}{c} \text{SO}_2 > \text{CH}_4 > \text{H}_2 \\ T_c \quad 630 \text{ K} \quad 190 \text{ K} \quad 33 \text{ K} \end{array} \quad (\text{extent of adsorption})$$

For non-polar gases,

$a \propto \text{Molar Mass}$

In polar & non-polar generally polar has larger value of α .

$$\alpha_{\text{NH}_3} > \alpha_{\text{N}_2}$$

$$\alpha_{\text{H}_2} > \alpha_{\text{N}_2}$$

- c) It is reversible in nature.
- d) Physical adsorption follows the Chatelier's principle.

- As we $\uparrow P$, extent of adsorption \uparrow while on $\downarrow P$, extent will \downarrow .
- On $\uparrow T$, extent of adsorption \downarrow
- e) Extent of Adsorption will increase on increasing surface area of adsorbent.
- f) Enthalpy change will be of order 20 to 40.
- g) It is multilayered phenomena.

ii) Chemical Adsorption / Chemisorption :-

- Particles of adsorbate & adsorbent are held together by chemical bonds.
- a) It is highly specific in nature.
→ For eg,
 O_2 combines with metals while H_2 combines with transition metal.
- b) Extent of adsorption also depends on nature of adsorbate.
- c) It is irreversible in nature.
- d) On \uparrow temp. (in low temp. range) extent of adsorption \uparrow coz that energy is used to provide necessary activation energy.
- e) On $\uparrow P$, Extent \uparrow but on $\downarrow P$ it will not change.
- f) Enthalpy change will be of order $80-240 \text{ kJ/mol}$
- g) On \uparrow SA of adsorbent, adsorption will \uparrow
- h) It is unlayer phenomena.

Note : Physisorption of gas adsorbed at low temp. may get converted into chemisorption at high temp.

- Freudlich adsorption isotherm (1909) :

Freudlich proposed a relationship b/w extent of gases adsorbed on a solid surface and pressure of gas.

$$\frac{x}{m} = kp^{1/n}$$

where,

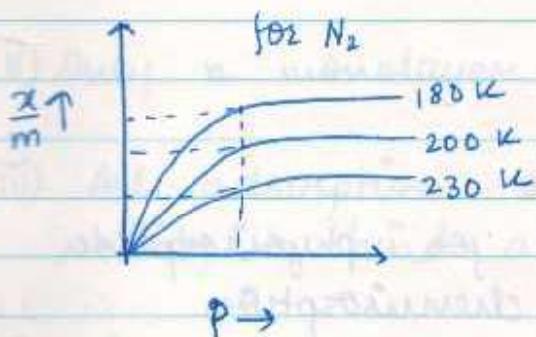

$\frac{x}{m}$ → extent of adsorption

k → constant

P → Partial pressure of gas at eq.

x → mass of adsorbate

m → mass of adsorbent

Probable values $\Rightarrow (0 < \frac{1}{n} < 1)$

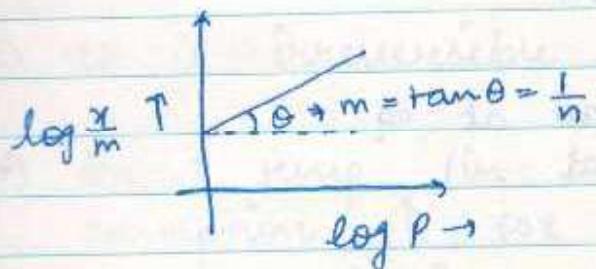

Calculation of 'n' :-

If a graph is plotted b/w $\log \frac{x}{m}$ v/s $\log P$ & it comes out to be straight line then gas is said to be following freudlich adsorption isotherm. Value of 'n' can be calculated from slope of this line.

$$\frac{x}{m} = kP^n$$

$$\log \frac{x}{m} = \log k + \frac{1}{n} \log P$$

$$y = c + mx$$

Limitations,

- Freudlich fails at high pressure
- His isotherm gives good results for physisorption but it is not suitable for chemisorption.
- Adsorption of solute from solution :-

Exact mechanism is not known for this adsorption but still there are certain observations.

- i) On $\uparrow T$, $\frac{x}{m} \downarrow$
- ii) On \uparrow surface area of adsorbent, $\frac{x}{m} \uparrow$
- iii) $\frac{x}{m}$ depends on nature of adsorbate
- iv) $\frac{x}{m}$ also depends on conc. of solⁿ at eq.

$$\frac{x}{m} = K C^n$$

where,

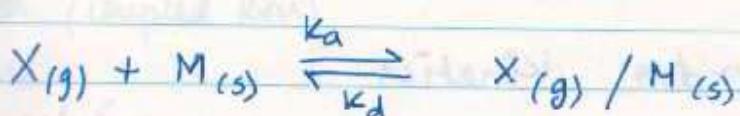

$C \rightarrow$ conc. of solⁿ at eq.

Langmuir adsorption isotherm (1916):

It is based on KTG.

Assumptions,

- i) all gases are considered as ideal
- ii) Only a monolayer is formed
- iii) All adsorption sites are equivalent w.r.t. their ability to bind a particular adsorbate particle.
- iv) Once the adsorbate molecules are adsorbed, they become localised.

Let σ be the fraction of sites occupied.

$$\text{Rate of adsorption } (\tau_a) = K_a P_x (1 - \theta)$$

$$\text{Rate of desorption } (\tau_d) = K_d \theta$$

At equilibrium,

$$\tau_a = \tau_d$$

$$K_a P_x (1 - \theta) = K_d \theta$$

$$\Rightarrow \theta = \frac{K_a P_x}{K_d + K_a P_x} \quad \Rightarrow \theta = \frac{K P}{1 + K P} \quad \text{where } K = \frac{K_a}{K_d}$$

$$\text{Extent of adsorption } \left(\frac{x}{m}\right) \propto \theta$$

$$\frac{x}{m} = K' \theta$$

$$\Rightarrow \frac{x}{m} = \frac{K' K P}{1 + K P}$$

$$\Rightarrow \boxed{\frac{x}{m} = \frac{a P}{1 + b P}}$$

a. a & b are called Langmuir constants

b. At low pressure

$$1 + b P \approx 1$$

$$\frac{x}{m} = a P$$

$$\boxed{\frac{x}{m} \propto P}$$

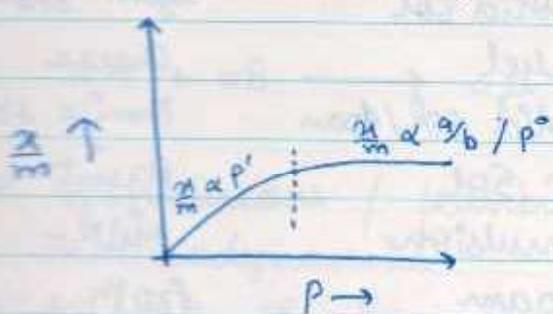

Fist order kinetics

At high pressure,

$$\frac{x}{m} = \frac{a}{P^0 + b} = \frac{a}{b}$$

zero order kinetics

$\frac{x}{m}$ is independent of pressure

* Catalysis :

- catalysts are the substances which change rate of chemical reaction without quantitatively participating in it. & this whole phenomena is called Catalysis.

Catalysis

Types

- Homogeneous
- Hetero
- Positive
- Negative
- Auto
- induced (coupled Rxn)
- Enzyme
- Shape selective

Basic terms

- Activity
- Selectivity
- Promotes
- Poison

Theories

- Intermediate theory
- Complex form theory
- Poison theory

Old Theory

Modern Theory

* Colloids :-

Dispersed Phase	Dispersion Medium	Colloid	Example
S	S	Solid sol	Lyon stones
L	S	Gel	Cheese
G	S	Solid sol/foam	Pumice stone
S	L	Sol	Paints
L	L	Emulsion	Milk
G	L	Foam	Sooth
S	G	aerosol	Smoke, dust
L	G	aerosol	Fog, mist

* Charge on colloid :-

Colloid as a whole is neutral but generally charge on dispersed phase particles is called charge on colloid. Actually particles of dispersed phase have equal but opp. charge.

* Origin of charge :-

- i] Frictional electrification
- ii] Dissociation of surface molecules
- iii] Preferential adsorption of ions from solⁿ
- iv] Capture of e⁻
- v] Dissociation of molecular electrolytes on surface of particles.
